ABSTRACT

There is little information on the oral health status of visual impairment in Thailand. **Objective:** To investigate the oral health status and dental treatment needs of visual impaired Thai. **Method:** The subjects were 146 visual impairment (70 males and 76 females, mean age 48.8 ± 5.9), who live in Phitsanuloke, Thailand. Information on self-perceived oral health problems, oral function and oral health behavior was obtained via questionnaires. Oral examinations investigated the Decay Missing Filling Teeth (DMFT), Simplified Oral Hygiene Index (OHIS) and prosthetic needs index. **Results:** The mean DMFT score was 16.0 (DT=4.4, MT=10.2, FT=1.4), the mean number of teeth present was 15.5. 35% of subjects needed dental fillings and 12.3% required tooth extractions. 34.8% had periodontal disease and mean OHIS score were 2.52. Thirty-eight percent of subjects need both upper and lower partial dentures. Visual impaired suffer from oral function problems (speaking problem 26.5%, swallowing problem 32.6%, tasting problem 29.2% and chewing problem 45.2%). **Conclusion:** The oral health status of visual impairment was poor due to high levels of tooth loss, caries experience and periodontal disease. Therefore, it is important to have a proper preventive approach and service delivery programs to improve the oral health condition of this population.

Key words: DMFT, oral health status, treatment needs, visual impairment

ABSTRAK

Kebutuhan perawatan dan status kesehatan gigi dan mulut tuna netra di Phitsanuloke, Thailand. Tidak banyak informasi mengenai status kesehatan gigi dan mulut pada tuna netra di Thailand. **Tujuan:** Menganalisa status dan kebutuhan perawatan kesehatan gigi dan mulut pada tuna netra di Thailand. **Metode:** Subjek penelitian ini adalah 146 tuna netra (70 laki-laki dan 76 perempuan dengan rerata umur 48,8±5,9) yang bertempat tinggal di Phitsanuloke, Thailand. Kuesioner digunakan untuk mendapatkan informasi mengenai persepsi subjektif masalah kesehatan gigi dan mulut, fungsi oral dan perilaku. Pemeriksaan oral dilakukan untuk menganalisa Decay Missing Filling Teeth (DMFT), Simplified Oral Hygiene Index (OHIS) dan prosthetic needs index. **Hasil:** Rerata DMFT subjek yang diperiksa adalah 16 (DT=4,4, MT=10,2, FT=1,4), rerata jumlah gigi yang masih ada 15,5. 35% memerlukan tambalan gigi dan 12,3% membutuhkan pencabutan gigi. 34,8% memiliki penyakit periodontal dengan rerata OHIS 2,52. 38% subjek membutuhkan gigi tiruan sebagian atas dan bawah. Tuna netra mengalami masalah fungsi oral (masalah dalam berbicara 26,5%, masalah penelanan 32,6%, masalah pengunyahan 29,2% dan masalah pengecapan 45,2%). **Simpulan:** Status kesehatan gigi dan mulut tuna netra rendah karena kehilangan gigi yang banyak, karies dan penyakit periodontal. Oleh karena itu sangatlah penting untuk memiliki pendekatan program preventif yang tepat untuk meningkatkan kesehatan gigi dan mulut populasi tersebut.

Key words: DMFT, oral health status, treatment needs, visual impairment
INTRODUCTION

Oral health is linked to good general health and happiness, and there is evidence that esthetically acceptable and functionally adequate dentitions affect self-esteem, confidence, and socialization. Vision may be the most important sense for interpreting the world around us, and when sight is impaired, it can have detrimental effects on physical, neurological, cognitive, and emotional development. Visual impairments vary from total blindness to slight limitations of size, color, distance, and shape. Visual impairment relates to a person’s eyesight which cannot be corrected to normal vision. Physical, social and information are barriers that impact on oral health of visual impairment. Visual impairments tended to have a larger amount of dental plaque and were at a higher risk for dental diseases than were sighted individuals.

Oral health and dental care of the disabled has generally been poorer than the general population. High DMFT/DMFT scores were manifest in groups of visually impaired children in many countries. Poor oral hygiene, gingivitis and periodontal diseases have been reported among visually impaired children in studies from India, Iran, and Turkey. Inability to visualize the plaque on tooth surfaces resulting in inadequate plaque removal and therefore the progression of dental caries and inflammatory disease of the periodontium of visual impaired patients.

There is little information on the oral health status of visual impairment in Thailand. The oral health status of visual impairments should be investigated so their health care needs can be determined and preventive dental procedures can be implemented. Therefore, the purpose of the present study was to investigate the oral health status and treatment needs of visual impaired Thai.

METHODS

The subjects for this cross-sectional study were drawn from visual impaired people aged 20 years or older with a simple sampling form Phitsanulok, Thailand. A total of 146 people (70 males and 76 females; mean age=48.8 years; SD=6.9) agreed to join the study and finger printed the informed consent form. A questionnaire survey administered by interview and oral examination were conducted. This study protocol was approved by the Naesuan University Ethical Committee on Human Rights, Thailand.

Oral Function

Oral function was evaluated by the response to the following questions: “Do you have, or have you had, speaking problems”? (swallow problem, taste problem, and chewing problem). The interviewer asked participants to respond to each question by “yes” or “no”.

Oral examination

The examination procedures, instruments and diagnostic criteria followed those recommended by the World Health Organization. Tooth status was recorded using the DMFT index. The community periodontal index (CPI) was used to assess the periodontal status. In addition, prosthetic status and treatment needs were classified and recorded according to WHO criteria. Oral hygiene was assessed using the Simplified Oral Hygiene Index (OHI-S) of Green and Vermillon (1964).

Salivary flow rate

All subjects abstained from smoking, eating and drinking for 2 hours prior to the measurement of salivary flow rate. Resting whole saliva was collected for 5 minutes by a spitting method. Stimulated whole saliva was collected by a mastication method, in which subjects were asked to chew a small paraffin block for 5 minutes. Subjects were classified into 2 groups according to salivary flow rates. Subjects whose resting salivary flow rate less than 0.1 mL/min and stimulated flow rate less than 0.5 mL/min were classified as hyposalivation.

Statistical analyses were performed with the SPSS 17 software program and *p*<0.05 accepted as the level for statistical significance. The Chi-square test was used to compare categorical or nominal level data. Analysis of variance (ANOVA) was used to test for differences of mean scores among two or more independent groups of interval level data.

RESULTS

The number of subjects aged 20-69 years was 120 (82.19%) and those aged 60 years and older were 26 (17.81%). Among all subjects, 39.8% of those lived with only husband or wife, 56.1% lived with their family members, and 4.1% lived alone. Most subjects were non smokers (97.3%). Systemic diseases were observed in 77.2% of subjects: hypertension 47.3%, diabetes mellitus 26.3%, heart disease 7.5% and other disease 11.7%. Moreover 74.9 % of subjects routinely used medicines. The oral hygiene practices of subjects were: 38.4% claimed to brush their teeth once a day, 61.6% claimed to brush their teeth twice or more per day. 32.1% of all subjects never visited dentist, only 13.2% of subjects had regular dental check ups.

The numbers of present teeth, decayed teeth and filled teeth by age and gender were showed in Table 1. Subjects in the 60 years and older age group had significantly lower number of present teeth than those in the 20-59 years old age group. The mean number of filled teeth was low and less than 2 tooth among all subjects. The mean OHIS score of this study was 2.52. One-third of subjects (34.37%) had periodontal disease.
Among all subjects, 32.6% complained about swallowing problems, 26.5% had speaking problems, 29.7% complained about taste problems and 45.2% had chewing problem. Table 2 shows the percentage of subjects with tooth, periodontal and prosthetic treatment needs. About 35% needed dental fillings and 12.3% required dental extraction. Of all subjects, 36.2% needed professional scaling and 26.6% required complex treatment for managing deep periodontal pockets. In total, 38.2% needed both upper and lower prostheses. The mean salivary flow rate of resting saliva is 0.3ml/min and stimulating saliva flow rate is 0.43ml/min. 43.8% of all subjects had hyposalivation (resting salivary flow rate <0.1 ml/min and stimulating salivary flow rate <0.5mg/min).

### DISCUSSION

This is the first comprehensive oral health survey of visual impaired population in Thai. It showed that the visual impairment have high caries experience, high percentage of periodontal disease and poor oral hygiene. Oral disease represents a major health problem among individuals with disabilities. The prevalence and severity of oral disease among this group are higher when compared to the general population.

The caries experience variables in this study were higher for MT, DT, and DMFT higher than those reported in the national oral health survey in 2012. Of all subjects, 36.2% needed dental fillings and 12.3% required dental extraction. Of all subjects, 36.2% needed professional scaling and 26.6% required complex treatment for managing deep periodontal pockets. In total, 38.2% needed both upper and lower prostheses. The mean salivary flow rate of resting saliva is 0.3ml/min and stimulating saliva flow rate is 0.43ml/min. 43.8% of all subjects had hyposalivation (resting salivary flow rate <0.1 ml/min and stimulating salivary flow rate <0.5mg/min).

</table>
have been observed in children with disabilities.\textsuperscript{19,20} These results may be related to the low physical abilities of these individuals and consequent difficulties in tooth brushing. Oral health may be affected by the followings: limited understanding on the importance of oral health management, difficulties in communicating oral health needs anticonvulsant medications that impact upon gum health, and a fear of oral health procedures.\textsuperscript{21,22} Physical restraints and general anesthesia are commonly used to treat adults with disabilities who have fear and communication difficulties related to oral health.\textsuperscript{23}

This study showed that visual impairment had poor oral hygiene, consistency with previous study. The oral hygiene of the blind population is significantly worse than in an equivalent sighted one.\textsuperscript{24} Visual impairments were less knowledgeable about their oral care and did not realize the need to have regular dental visits.\textsuperscript{25,26} This study found that visual impaired person had low salivary flow rate, might be cause of their visual problems, consistency with previous study reported that light is associated with salivary flow rate.\textsuperscript{27} Hyposalivation is a risk factor not only for dental caries and periodontal disease but also for taste disturbances, speaking problems, swallowing problems, poor chewing ability and malnutrition.\textsuperscript{28} Monitoring salivary flow is an important measure in the care of visual impairment. This will alert dentist and dental health worker to mention not only oral health problem but oral impairment. This will alert dentist and dental health worker to mention not only oral health problem but oral impairment.

The inherent problems of and limitations imposed on patients by their sensory impairment should be aware by dental professionals.\textsuperscript{5} They should know the best ways to communicate with visually impaired patients and to make them familiar with the dental setting. Maintaining oral health is central to a high quality of life because it limits the risks of disease.

These findings reflect serious lack of access to dental treatment of visual impaired Thai. Cost of the service, transportation, lack of trained and experienced dentists were a barrier to receiving dental care.\textsuperscript{30} Other barriers to equal access to dental treatment for individuals with disabilities include inadequate facilities due to restricted financial resources and complex treatment needs requiring special care or general anaesthesia.\textsuperscript{31}

Oral hygiene instruction is important for prevention and treatment of oral conditions in visual impaired patient as it provides basis for good oral health throughout life. Giving good oral instructions and tactile devices to improve the tooth-brushing skills of visual impairments is considered the most important part of oral hygiene education.\textsuperscript{32,33} Adequate oral hygiene instructions may have a positive impact on individuals’ oral hygiene habits and periodontal status, thereby maintaining or improving individuals’ self-esteem.\textsuperscript{34} Preventive approach is essential for these special groups of visual impairment and dentist role is very essential as he can provide proper oral health education and help theses population to live a healthy life.

CONCLUSION

The oral health status of visual impairment was poor due to high levels of tooth loss, caries experience and prevalence of periodontal pockets. Oral health and oral function amongst the visual impairment is a public health concern. There is a need to develop appropriate education and service delivery programs to improve the oral health conditions of this population. In addition, the oral hygiene habits of individuals with disabilities can be improved by close monitoring and periodic dental check-ups.
